

# Exploring Distal Enhancers Through Histone SNPs

Chris Seward, Stubbs Lab

Cell and Developmental Biology

Institute for Genomic Biology

# Molecular Roots of the Social Brain

- ▶ Project to identify **gene networks** that respond to **social stimuli** in mice, honeybees, and stickleback fish.
- ▶ Utilized **RNASeq** and **ChIP-seq** after social stimulus to identify differentially expressed genes and differentially accessible regulatory elements
- ▶ In Honeybee, studies revealed stronger differences in histone modifications **between colonies**, than due to social stimuli
- ▶ Additionally, it is **always difficult** to assign distal enhancers to the genes they regulate

# Differential Histone SNPs

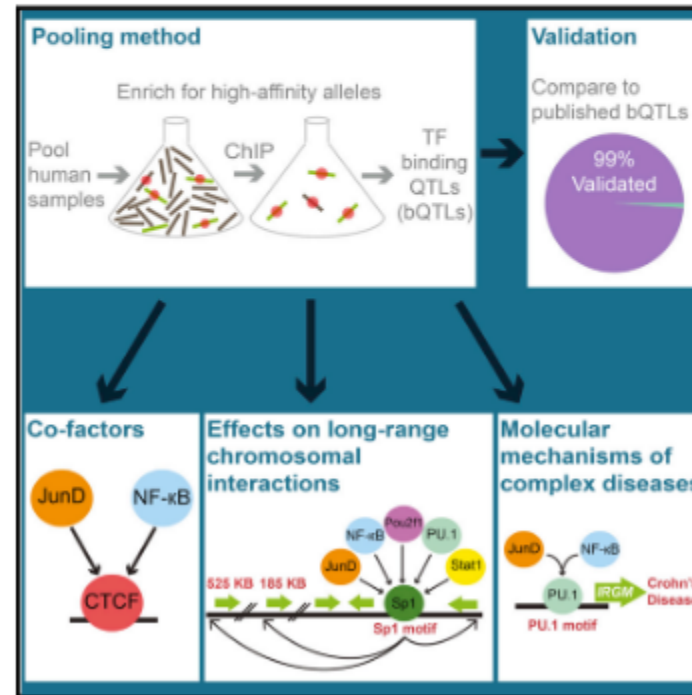

- ▶ Can SNPs explain differences we see between colonies in histone peaks?
- ▶ Recent study in humans examined **SNP preference** in pooled histone and TF ChIP peaks .....▶
- ▶ Can we apply a similar approach to data we have **already collected** from honey bee and mouse?
- ▶ Can we also use this data to help **link distal peaks to genes**?

### In Brief

Examination of thousands of human genetic variants that affect transcription factor binding demonstrates a role for natural gene variation in chromosomal architecture and illustrates the efficiency and economy of using pooled samples for these analyses.

# Differentially Enriched Histone SNPs Pipeline

- ▶ When we do ChIP we collect input DNA, basically genomic DNA
- ▶ Pooling of all input DNA gives ~30x coverage → call SNPs in population
- ▶ Also pooled control H3k27ac peaks from each colony → call peaks
- ▶ Then checked SNP frequency in gDNA vs. inside Histone peaks

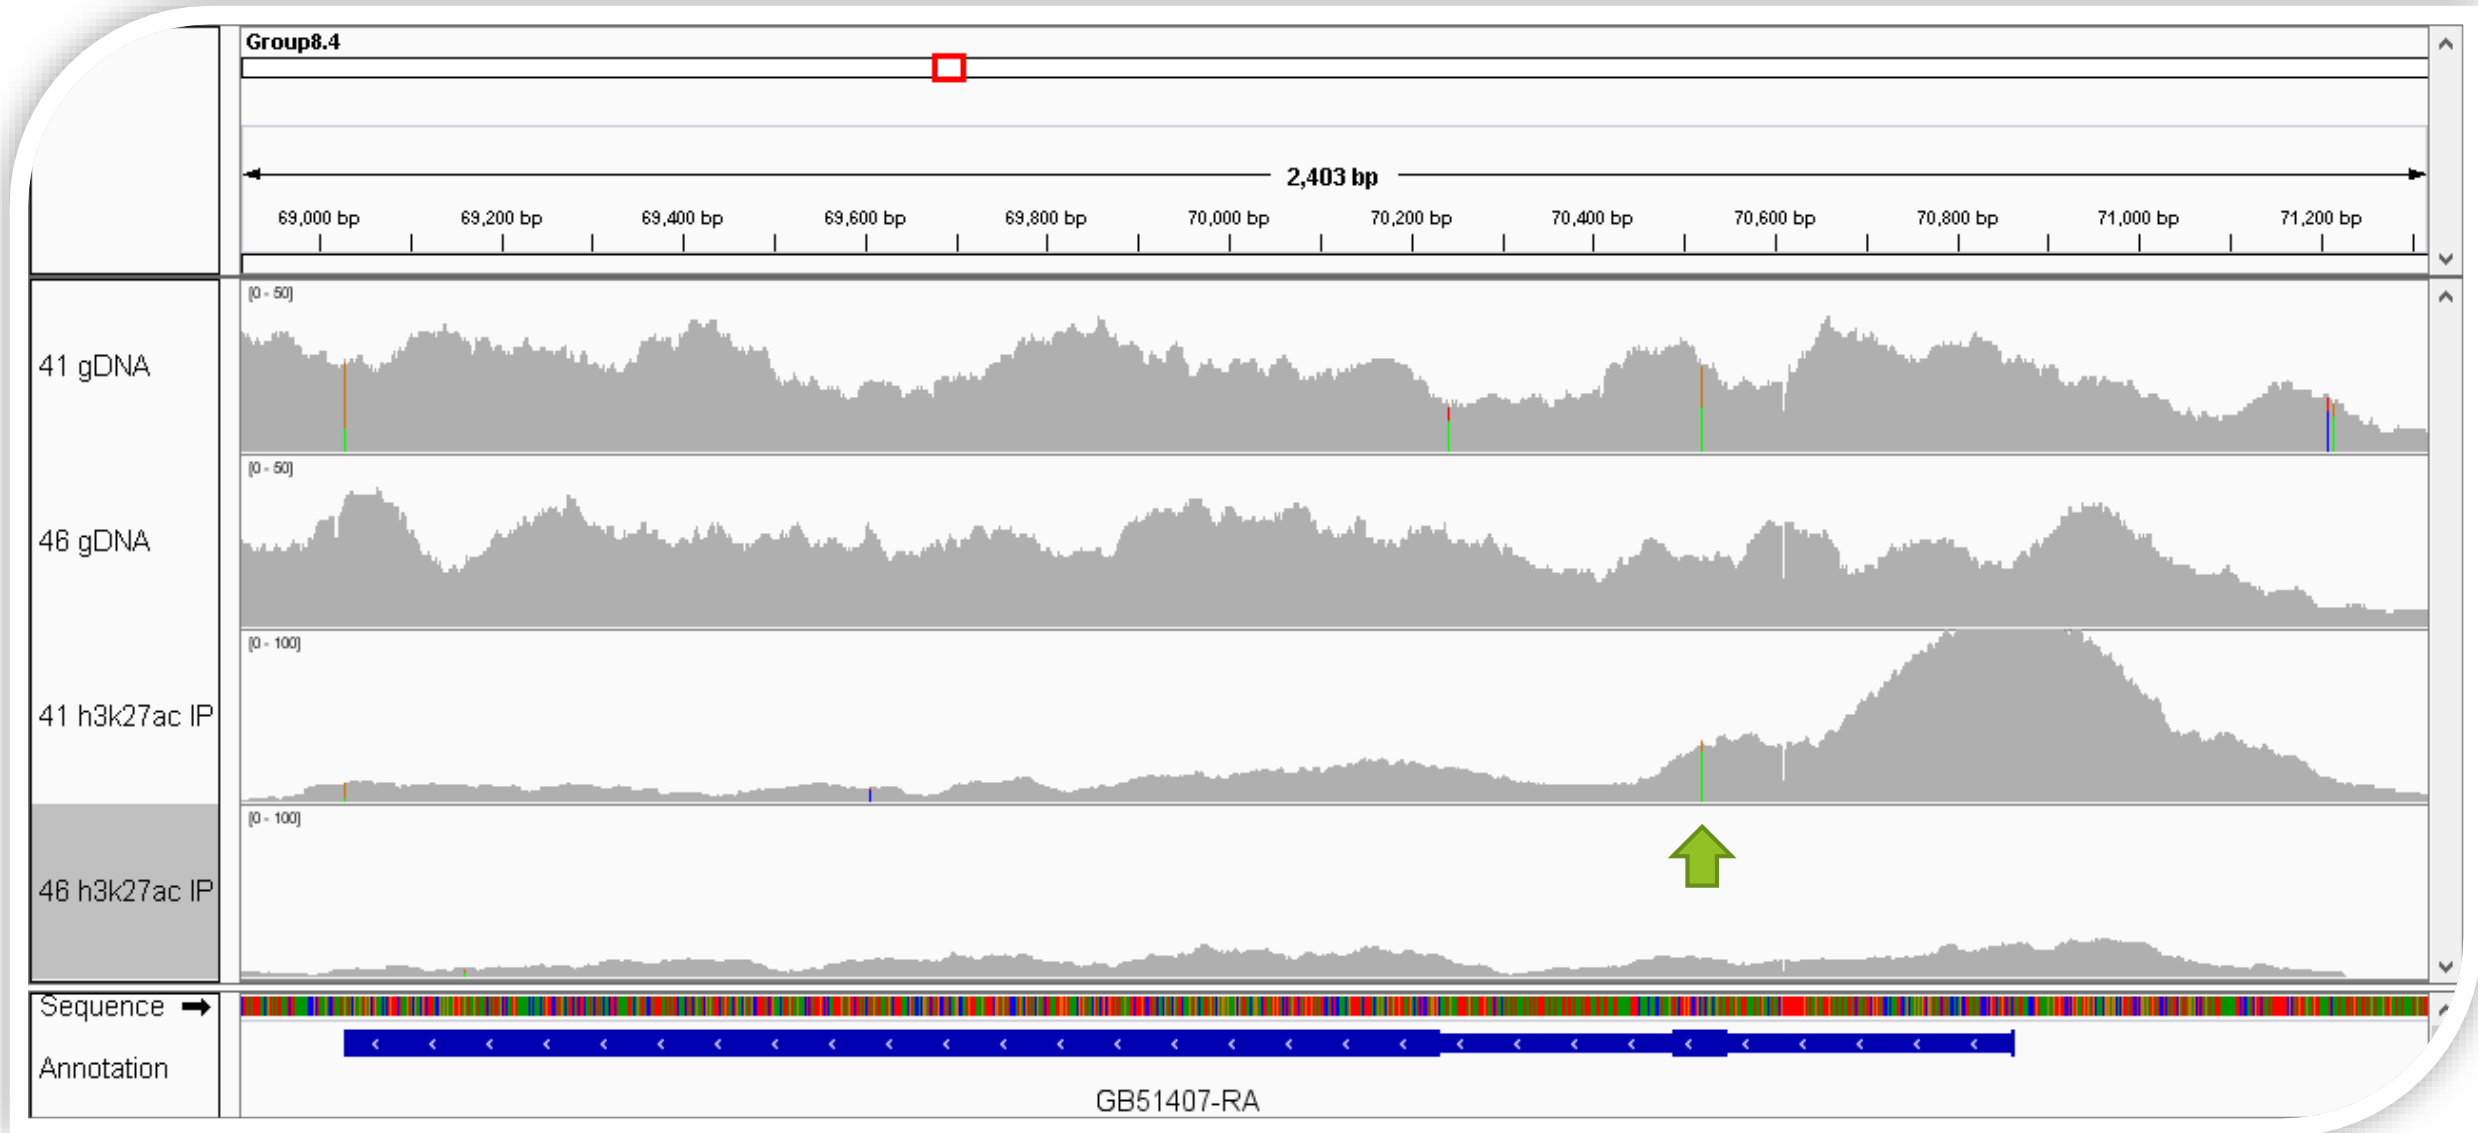

# Two Possible Histone SNP Effects

- I. Genomic DNA has a particular SNP frequency in the pool, eg 50%, but Histone peak has a significantly different SNP frequency, eg 90%
- II. One of the two colonies has a SNP, but the other colony does not. Colony with the SNP has a peak, but the other colony does not.

Variation could be from heterozygous DNA OR from multiple individuals in pool

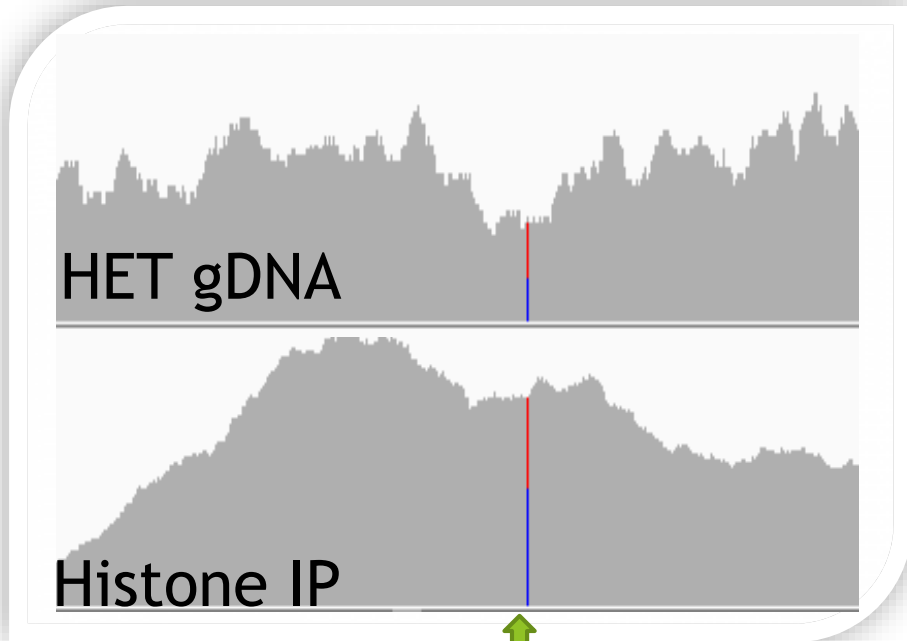

# Example: Unnamed Zinc Finger

Histone peak is only present in colony that has SNPs  
One SNP allele is preferentially found in 83% of histone reads vs. 48% of genomic reads

# Second Approach: BL6/CD1 Hybrid Histone SNPs

- Generating a Hybrid Mouse line allows for testing with less coverage

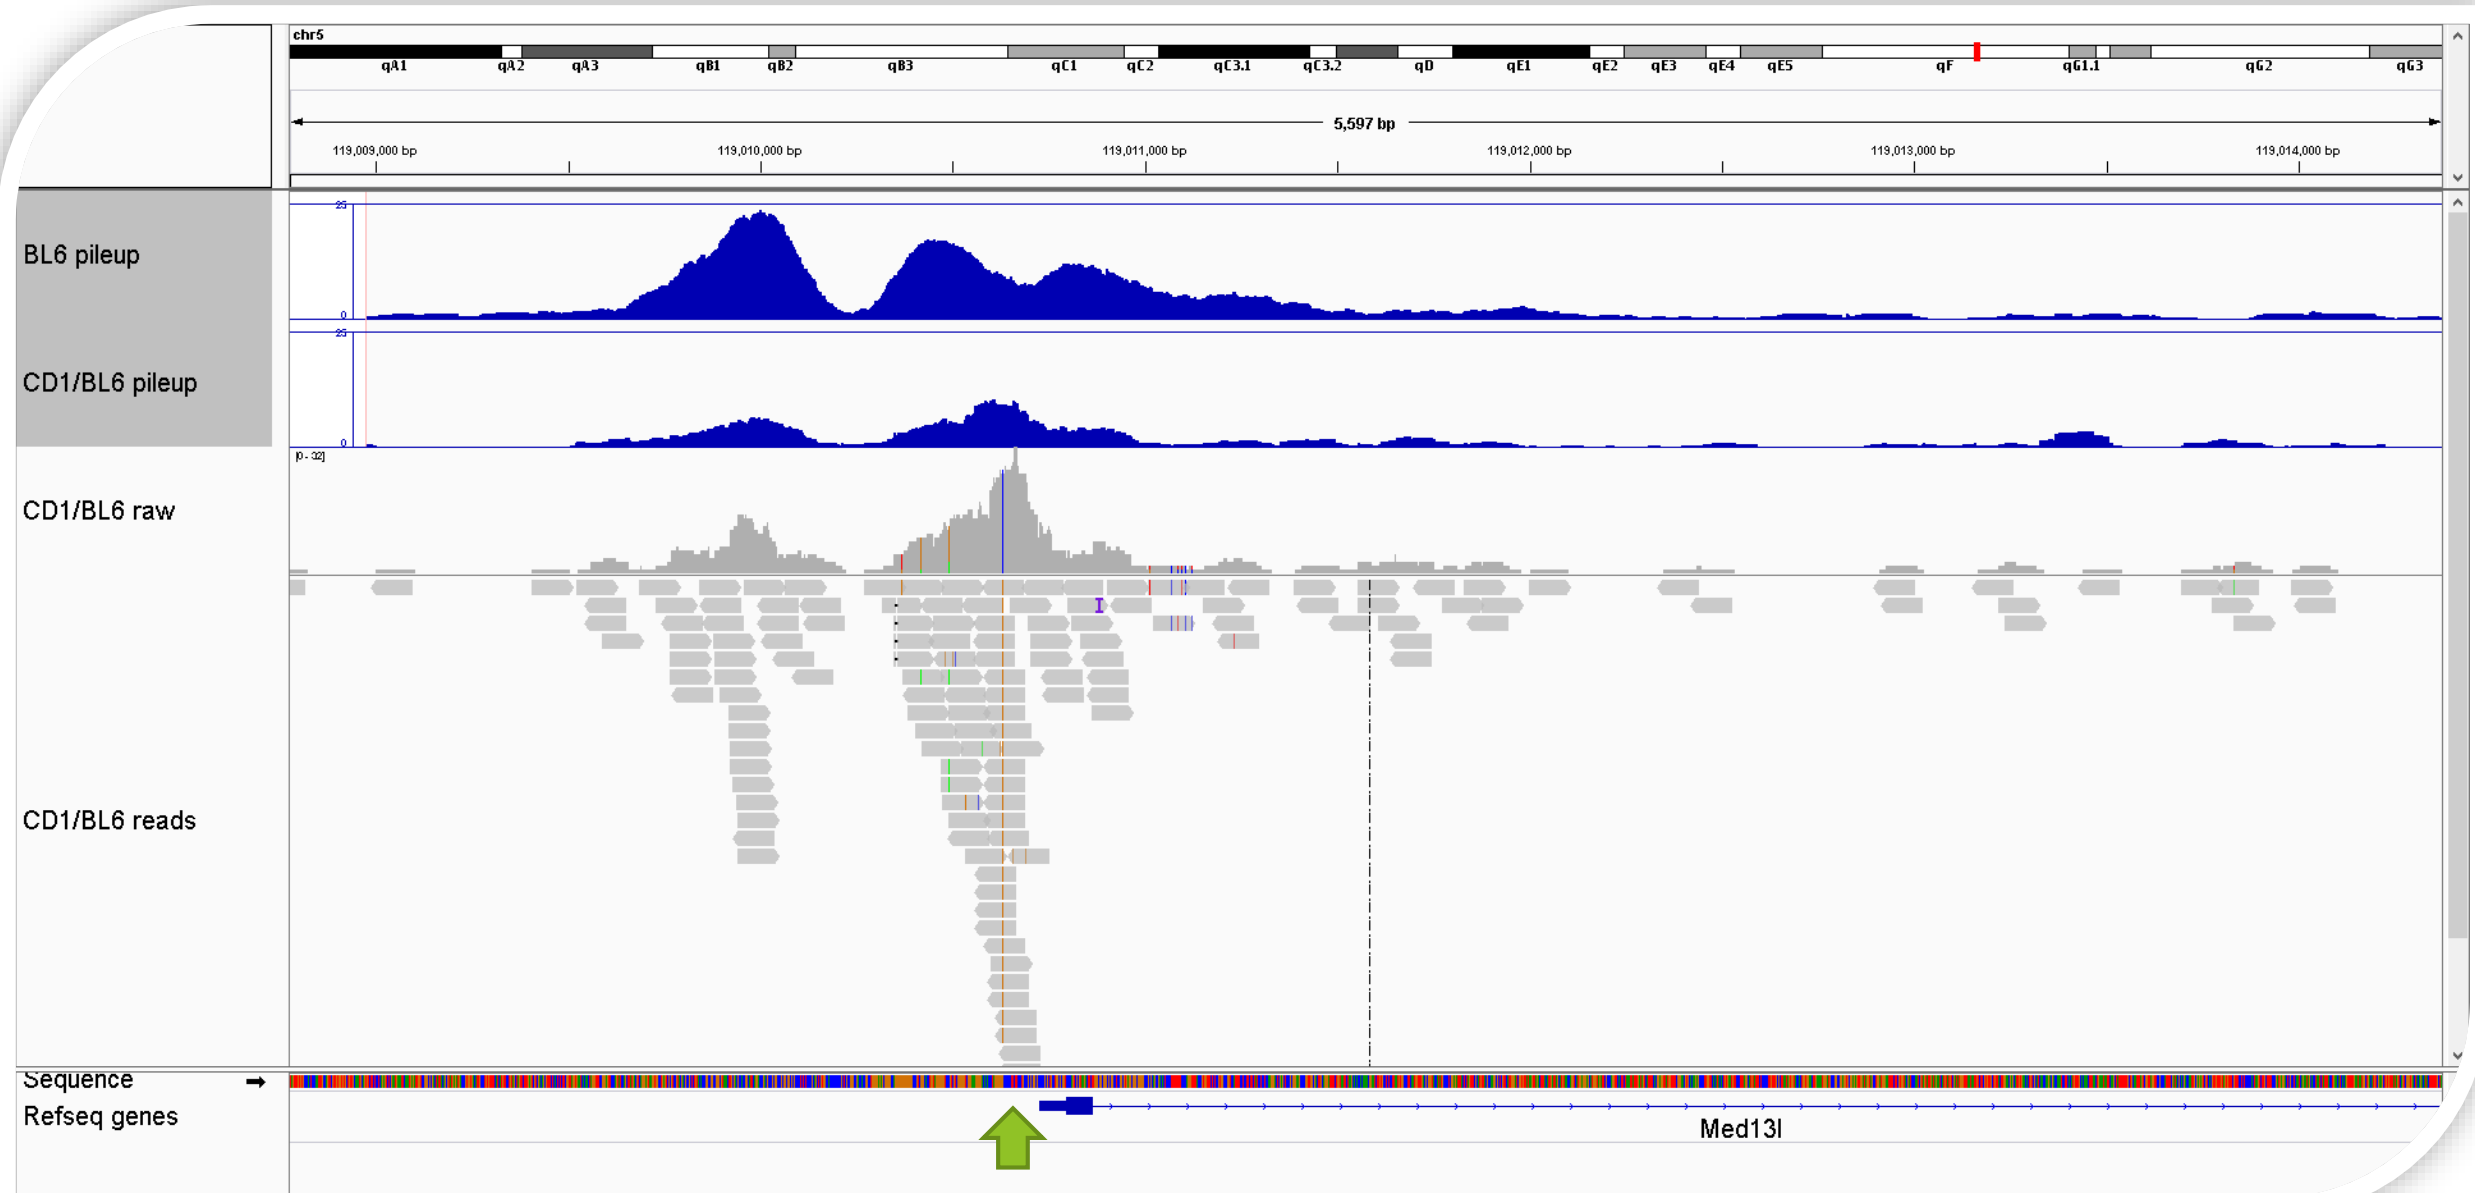

No preference

Strong preference  
for one genotype

# Example: Med13l (100/0 SNP)

# Future Directions

- ▶ Re-run improved Histone SNP calling pipeline on honeybee dataset, taking **ploidy** into account
- ▶ Bring in **gene expression data** to see if Histone SNPs also change gene expression pattern of nearby genes, allowing us to link **distal peaks** to the genes they regulate
- ▶ Identify co-occurrence of Histone SNPs with **regulatory motifs**
- ▶ Use **CRISPR** to test hypotheses and **validate** methods *in vivo*
  - ▶ Eg. Introduce a SNP predicted to be influential to a primary cell line and see if that alters nearby chromatin and expression
